Abstract: Development of a heuristic algorithm where there is a control measure to cost is presented. The study developed a flow chart of heuristic algorithm and dynamic programming was noted as optimization tool to obtain the cost function. The results obtained moved towards the left which showcased reduction in the cost function (Z). A control measure to cost function was obtain in order to check the cost function in terms of trend, this is denoted as Zcheck.

Keywords: Heuristic algorithm, control measure, cost function, dynamic programming, optimization.

1. INTRODUCTION

The need for significant increase in productivity of several industries calls for the use of queuing system to reduce waitingtime or down time [1]. The waiting time could be reduced or even eliminated by providing additional service facilities [2]. The study of queuing models has been of considerable active interest ever since the birth of queuing theory at the beginning of last century. Queuing theory continues to be one of the most extensive theories of stochastic models. It has attained a progressive movement both in methodology and application. In terms of innovative analytic treatments as it concerns its theoretical development, a tremendous advancement has been recorded. Also, queuing theory provides an efficient mathematical framework for the study of several congestion phenomena arising in diverse application areas which include,

www.scirj.org © 2022, Scientific Research Journal <u>http://dx.doi.org/10.31364/SCIRJ/v10.i1.2022.P0122902</u> This publication is licensed under Creative Commons Attribution CC BY. production lines of manufacturing industries, banks, telecommunications, marking of papers, etc.

In traffic jams queues also occur, other areas where queues occurs include tool booths, supermarkets, and airport. Queues also occur based on internet and telephone system. In hospitals, doctors operate using queuing system, as well as jobs on a machine. All these waiting are disliked by the customers and the servers, and as a result lead to customers' dissatisfactions. Invariable, owing to customer's dissatisfactions, both productivity and profit are negatively affected. Queues are predominate in manufacturing companies such as First aluminum Port Harcourt, Vinal aluminum Irete, Eagles cement Port Harcourt, Seven up bottling company Aba, and Coca cola bottling company Aba. As such, this calls for improvement so as to increase the productivities of these company. This study emphasizes the need to reduce queues so as to increase the profit margins made by these companies. Considering the level of queuing problems, it is obvious that queuing studies need persistent effort aimed at eliminating or reducing queues.

The research on optimization of queuing system based on computer simulation is discussed. The study showcased that each consumer hoping to complete a transaction must pass through the road queuing system to a prominent position. A new design of metaheuristic search called improved monkey algorithm based on random perturbation for optimization was critically examined [1, 2]. The study aimed at presenting a design of a metaheuristic search that provides a solution for optimization issues [2].

A multi-level (m - level) mechanism and evolution strategies (ESs) was introduced in order to address a class of global optimization problems that could benefit from fine discretization of their decision variables [3].

Heuristic algorithms which involve the decision tree method and the greedy search algorithm help solutions with less time and improved solution's quality [4] infinite monkey theorem and heuristicity were introduced such that heuristicity can be analysed using infinite metaheuristics, are a class of approximate methods, which are designed to attack hard combinational optimization problems [5,6]. Future of metaheuristic algorithm was examined so as to ensure its application especially in engineering and sciences [7].

The Locus mutation method is a gene-dependent local mutation operator that involves genes with different multation rates [8].

Heuristic algorithm for combined heat and power system was studied. In the research, residential buildings were taken into account based on components interactions. the idea is to obtain a process that decomposes the three energy vectors needs which are electrical, thermal and hot water. Interconnection and operational constraints were taken into account. Series of simulations were used on residential pilot with a nanocogenerator unit of about 25-30% energy saving when compared with a meta heuristic genetic algorithm method [9]. Algorithms and flowcharts are two important tools that explain process of a program [10].

Generally, optimization has been applied in many fields in order to transform the performance of products, processes, and interventions [11]. The application of dynamic programming to the identification of optimal parameters of tree-structure energy pipeline networks was determined. They study presented unified conceptual and mathematical statement. A single stage manufacturing system with setups that give rise to a single part type in order to satisfy demand was examined. In the study dynamic programming was employed which is in form of Markov Decision process in order to minimize backorder, lost sales and set up costs, [12, 13]. An iterative algorithm for the max-min knapsack problem with multiple scenarios was determined. The method was evaluated using vet bench mark from recent literatures. Results obtained were compared and it provided a better bounds than already published literature [14].

An approach was made to a selection hyper-heuristic algorithm for multiobjective dynamic economic and environmental load dispatch. The study established the amountof electricity generated from plants during the planning period to meet load demand as energy consumption costs is minimized. Unit commitment problem using an evolutionary algorithm and a plurality of priority list was determined base on energy management.

A heuristic algorithm for optimal service composition in complex manufacturing networks handled service composition in a cloud manufacturing environment that involves adaptive and optimal assembly of manufacturing service [15, 16, 17]. A heuristic algorithm based on line-up competition and granulized pattern searchforsolving integer and mixed integer non-liner optimization problems was examined. The algorithm treats multi-model problems as well as concurring with existing literature [18]. Various publications exist on queuing systems model. Majority approached the solutions separately. This work was aimed at studying a heuristic algorithm to obtain a control measure to cost function based on dynamic programming.

II. MATERIAL AND METHODS

2.1 Development of a heuristic algorithm

The heuristic algorithm was developed in line with the methods obtainable in mathematics and computer science [9]. These steps include problem definition, model development, specification of the algorithm, program testing and documentation.

In this study, the procedure for the flowchart of a heuristic algorithm is shown in Fig. 1. The processes include identification of the queuing problem, feasibility studies of the optimization method, decision, resort to optimization, choosing dynamic programming, obtain the cost function, obtain the control to cost function.

2.2 Determination of dynamic programming

In order to achieve a Maintenance constraint

This takes care of repair and upkeep of machines as described in equation.

Policy on queuing constraints

In this study the queuing policy ensures that the two constraints above are equal.

Objective function of the queuing model

The objective function in this study is to minimize the

total production cost.
Minimize
$$\sum_{i=1}^{m} \sum_{k=1}^{m} + \sum_{k=1}^{n} \sum_{j=1}^{m} C_{kj}X_{jk}$$

Summaryof the model

$$\sum_{i=1}^{n} \sum_{k=1}^{m} C_{ik} X_{ik} \qquad \sum_{k=1}^{n} \sum_{j=1}^{m} C_{kj} X_{kj}$$

Subject to the constraints

Time
$$\sum_{j=1}^{n} X_{ik} \leq T_i$$
 $i=1, 2, 3 --m$
Maintenance $\sum_{L=1}^{m} X_{kj} \leq R_i$ $j=1,2=...n$

Policy
$$\sum_{j=1}^{n} X_{jk}^{m}$$
 $X_{jk} = 0$

$$X_{ik}, X_{kj\geq} 0$$

Step one

Formulate the optimization equation

Minimize Z = f(x)

Subject to the constraints

Time
$$\sum_{j=1}^{n} X_{ik} \leq T_i$$
 (1)

Maintenance

(2) $\sum_{I=1}^{n} \sum_{I=1}^{m}$

 $\sum_{k=1}^{m} X_{ik} \leq R_j \qquad j=1, 2, \dots n$

www.scirj.org © 2022, Scientific Research Journal <u>http://dx.doi.org/10.31364/SCIRJ/v10.i1.2022.P0122902</u> This publication is licensed under Creative Commons Attribution CC BY.

Policy

 X_{ik} - $X_{kj} = 0$

Step two

Develop the necessary models and make necessary assumptions

Time is in minutes

Cost is in Naira

 $Z = \sum \left\{ \begin{array}{l} \displaystyle \bigoplus_{i} Lq \; (S_i) + C2 \; [\; \sum (S_i - n). \quad P_{si} \\ \\ \displaystyle (3) \end{array} \right.$

 $\sum\!P_{si} = P_{si} \ + \ P_{S2} \ + P_{S3} \ + P_{S4} \ + P_{S5} \ + P_{S6}$

(4)

n = 10, number of customers

 $C_1 = 0.3$, cost per customer

 $C_2 = 3$, cost per idle server

Where Z = cost function in Naira (\mathbb{N})

S= number of servers

Step six

```
Determine the Z_{check} using equation (5)
```

Step seven

Perform the analysis with excel software. The dynamic programming was applied so as to obtain the optimization cost function called "Z". In this process, necessary basic assumptions were made to enable the functionality of the method. Data from five companies were handled.

 $Z_{check} = \sum \left[C_1 . L_q (S_i) + C_2 \left[\sum (n - S_i) . Psi \right] \right]$

(5)

Considerations should be made for twenty four hours a day, this implies that the system is twenty four. Step three Determine the server utilization P_{si} , for the values of i ranging from 1 to K where K is 6. $Psi = \lambda (6) S\mu$ Summation of the above $:\sum_{I=1}^{k} Psi$ (7) Step four

Calculate the queue length L_q

 $L_q = \sum_{I=1}^{k} (n - S_i). P_{si}(8)$

Step five

Evaluate the cost function Z in equation (3)

Figure 1: Diagram showing connection of a queuing system of several sources and one departure.

III RESULTS AND DISCUSSION

Determination of a control measure to cost function

The evaluation of the control measure to cost function was achieved by dynamic programming. Twenty four systems with eight shifts were determined.

Tables 1 - 5 show the dynamic programming of data from First Aluminium and four other companies. Twenty four hourly systems are involved with three shifts per day. The service rate are kept constant at a value of four (4). The values of P, Lq, Z and Zcheck were obtained. The numerical values are used to show the relationship between the system and other parameters. The Z values moved downward, while Zcheck moved upwards to show control of trend.

Figure 2-6show the dynamic programming of data from First Aluminium and four other companies. Twenty four hourly iv. **CONCLUSION**

The observation of a heuristic algorithm where there is a control measure to cost function was successfully conducted. The results obtained showed that the higher the control measure to cost function, the lower the cost function. This was possible by the application of the working tool note as dynamic programming. The result obtained for the cost function moved towards the left which showcased reduction. A control measure to cost function was obtained in order to check the cost function in terms of trend, this is denoted as Zcheck.
